Skewness (Basics)

Task 3

Example: YouTube Video Views

A real-world example of right-skewed data is the number of views received by YouTube videos.

The dataset consists of the total views of videos uploaded to YouTube, ranging from zero views to billions of views.

Why is it right-skewed?

1. Natural Floor: A video cannot have negative views, so the minimum value is zero.

2. Majority of Videos: Most videos uploaded by ordinary users and small creators receive relatively few views, usually from zero to a few thousand.

3. Long Right Tail: A small number of popular videos, such as viral memes, music videos, and videos from famous creators, receive millions or even billions of views.

Conclusion

The data is right-skewed because most videos have relatively low view counts, while a few extremely popular videos have very high view counts. These unusually high values pull the mean to the right, making it generally higher than the median.
